PATENT

MOTOR VEHICLE WIPER COMPRISING A WEAR INDICATORBACKGROUND

This invention concerns the wiping means of the windows of motor vehicles and, more specifically, their wear.

A wiper blade equipped with its elastic wiper stem is a piece of the vehicle that wears out and which is necessary to replace regularly if one wants to guarantee a good wiping quality of the window. This proves to be even more important for the driving safety while one is using the wiper blade on the front windshield of the vehicle.

The sources of wear are numerous and the blade is susceptible to degrading as much at the level of the wiper stem as at the joints and the articulation mount that carries it.

For example, the wiper stem is susceptible to wear via friction but can also wear due to the deterioration of the material that it is made of.

The agents of such deterioration are principally:

- sun light, and more specifically, ultraviolet rays that light contains;
- oxygen because, even if the vehicle normally parks in a closed garage, thus sheltered from sunlight, it cannot be sheltered from oxidation;
- temperature, variations of temperature, and humidity;
- ozone and all electromagnetic radiation from the environment.

It appears to be thus pertinent to determine the lifespan of the wiper blade as a function of its time exposed to the air.

In addition, it is frequent that drivers are incapable of remembering when they last changed their wiper blades. In effect, such an operation is not generally entrusted to a vehicle repair specialist who can, for example, proceed to a systematic, regular replacement of the blades.

The goal of this invention is to allow the driver to determine the state of reliable wear of the wiper blades of his vehicle via a wear indicator that is representative of real wear constraints, and not dependent on sun exposure, that is to say the geographic or meteorological situation, or environment, for example pollution or altitude.

More precisely, the goal of the invention is a motor vehicle wiper comprising a wiper blade that is mounted on the free end of a wiper stem and pressing a wiper stem against a window to be wiper, in which the wiper is provided with an indicator comprising a substance based at least on an azo compound.

According to other characteristics of the invention;

- the inert and reactive layers are formed via ink in which an inert chemical pigmentation, defining a reference color, and a base organic pigmentation from the azo by-products are respectively created;

- the plastic support is in polyvinyl, polypropylene, or polyester and is covered with a protective layer fixed to the support film, in a detachable manner, via a semi-porous adhesive, this layer being pulled back during the mounting of the blade on the vehicle.

Other characteristics and advantages of the invention will become clearer in the reading of the detailed description that follows of one example of production, in reference to the attached drawings that represent, respectively:

- figure 2, cut view according to the plane II-II of the wear indicator according to figure 1.

The wiper blade 16 comprises an articulated structure 18 which carries, via claws 20, a wiping stem 22 generally created in a supple elastomer material. The articulated structure 18 is designed to press, with its entire length, the wiping stem 22 against a window to be wiped on the car,

The wear indicator 1 can also be attached to places other than the wiper, as long as it is easily visible while the wiper blade 16 is mounted on the vehicle.

One uses as azo by-product an alkaline-terrine salt azo with a sulfuric function. In other examples of production, the compounds used can be double-azos,

tetra-double-azos, or sulfuric function azos, taken individually or in combination. Preferably, the compound used furnishes a black color in such a way as to clearly distinguish the deep vibrant color that appears while the ink pigmented via the azo by-product is decomposed.

In the production example, the wear indicator is created in the form of a sticker label covered with a protective film 2 in polyethylene, resistant specifically to ultraviolet radiation and the oxygen in the air. This film adheres to the rest of the label via an adhesive semi-porous layer, in order to be easily detached during installation of the blade 16.

It appears more precisely on figure 2, which illustrates the label 1 in cut view, which figure makes up, in addition to the film 2, a support film 3 in polyvinyl, the lower face of which is coated with an adhesive 4 with a strong adhesion capability which allows the assurance of definitive, reliable fixation of the wear indicator 1 on the blade 16. Other plastic materials can be used for the support film, for example from polyester or polypropylene.

On the support film 3 is placed a first layer of ink 5, colored yellow with chemically inert pigments, and covered with a second layer of ink 6 of which the color is obtained via incorporation of organic pigments of azo by-products. At the fabrication of the wear indicator 1, the ink layers 5 and 6 are successively placed via a silk-screening technique.

The label is covered by a mask in the shape of a protective film 2, fixed to the support film 3 via a semi-porous adhesive 7. The mask is pulled back during the mounting of the blade on the vehicle while removing it from the support.

Over the course of time, chemical, physical, and mechanical attacks destroy the azo pigments of the upper layer 6. Once totally decomposed, it then displays the yellow lower layer, which hasn't been subjected to any attacks and which indicates an advanced state of wear of the wiping stem.

One has the advantage to choose an intense coloration for the lower layer 5 while it is under the form of a lower degree of oxidation. Thus, noticing the changing color of the wear indicator will be clearer.

The invention is not limited to the example of production described and represented. For example, in order to better control the kinetic of the degradation reaction, one can superimpose on the reactive layer a diffused layer that slows the contact between this layer and the chemical attacks. In addition, it is possible to mix the organic pigments to the mineral oxides, notably to some titanium oxide, in order to improve the sensitivity of the indicator.
